

**Dr. Arquímedes Ruiz Columbié**

Active Influence &amp; Scientific Management

Cloud seeding operations 2016 began over the Texas Weather Modification Target Area in March (March 7<sup>th</sup>, first operational day for the WTWMA target area) . This annual report is a compilation of the evaluation reports already made and published for four local projects: Panhandle, WTWMA, TPWMA, and STWMA target areas (EAA target area is included in the last one). A total of **306 clouds** were seeded and identified by TITAN in **119 target area operational days**. Table 1 summarizes the general figures:

**Table 1: Generalities**First evaluated operational day: **March 7<sup>th</sup>, 2016 (WTWMA)**Last operational day: **November 11<sup>th</sup>, 2016 (STWMA)****Season: 250 days****Net Number of operational days: 119**

Most active period: May to September: 103 ~ 87 % of the operational days,

Less active months:           March: 2           ~ 2 % of the operational days

November: 2       ~ 2 % of the operational days

According to the daily reports, operational days were qualified as:

**Seventy-eight with excellent performance****Twenty-eight with very good performance****Twelve with good performance****One with fair performance****Number of seeded clouds: 306**

(179 small seeded clouds, 81 large seeded clouds, 46 type B seeded clouds)

**Missed Opportunities: none** (with lifespan longer than 1 hour)

## Small Clouds

Table 2 shows the average results from the classic TITAN evaluations for the 179 small seeded clouds which obtained proper control clouds.

**Table 2: Seeded Sample versus Control Sample (179 couples, averages)**

Variable	Seeded Sample	Control Sample	Simple Ratio	Increases (%)
Lifetime	65.4 min	42.7 min	1.53	53 ( <b>40</b> )
Area	65.6 km <sup>2</sup>	42.5 km <sup>2</sup>	1.54	54 ( <b>39</b> )
Volume	220.0 km <sup>3</sup>	132.3 km <sup>3</sup>	1.66	66 ( <b>42</b> )
Top Height	8.9 km	8.1 km	1.10	10 ( <b>3</b> )
Max dBz	51.7	49.9	1.03	3 ( <b>1</b> )
Top Height of max dBz	3.7 km	3.7 km	1.00	0 ( <b>-1</b> )
Volume Above 6 km	57.3 km <sup>3</sup>	31.0 km <sup>3</sup>	1.85	85 ( <b>45</b> )
Prec.Flux	446.1 m <sup>3</sup> /s	264.3 m <sup>3</sup> /s	1.69	69 ( <b>49</b> )
Prec.Mass	2067.0 kton	775.7 kton	2.66	166 ( <b>126</b> )
CloudMass	168.6 kton	95.5 kton	1.76	76 ( <b>45</b> )
$\eta$	12.3	8.1	1.51	51 ( <b>56</b> )

Bold values in parentheses are modeled values, whereas  $\eta$  is defined as the quotient of Precipitation Mass divided by Cloud Mass, and is interpreted as efficiency. A total of **1181 AgI and 100 hygroscopic flares** were used in this sub-sample with an excellent timing (**95 %**), for an effective AgI dose about **65 ice-nuclei per liter**, which might have reached slightly higher levels in some individual cells. An excellent increase of 126 % in precipitation mass together with an increase of 45 % in cloud mass illustrates that the seeded clouds grew at expenses of the environmental moisture (they are open systems) and used only a fraction of this moisture for their own maintenance. The increases in lifetime (40 %), area (39 %), volume (42 %), volume above 6 km (45 %), and precipitation flux (49 %) are notable. There were slight increases in maximum reflectivity (1 %), and in top height (3 %). The seeded sub-sample seemed 56 % more efficient than the control sub-sample. Results are evaluated as **excellent** for this sub-sample.

An increase of 126 % in precipitation mass for a control value of 775.7 kton in 179 cases means:

$$\Delta_1 = 179 \times 1.26 \times 775.7 \text{ kton} \approx 174\,951 \text{ kton} \approx 241\,886 \text{ ac-f}$$

(mean layer: 14.8 mm  $\approx$  0.59 in)

## Large Clouds

The sub-sample of 81 large seeded clouds received a synergetic analysis. In average the seeding operations on these large clouds affected 82 % of their whole volume, with a perfect timing (100 % of the material went to the clouds in their first half-lifetime). A total of **2066 AgI and 185 hygroscopic flares** were used in this sub-sample for an effective silver iodide average dose near **95 ice-nuclei per liter**.

Also in average, large clouds were 23 minutes old when the operations took place; the operation lasted about 36 minutes, and the large seeded clouds lived 250 minutes (4 hours and 10 minutes).

Table 3 shows the corresponding results:

**Table 3: Large Seeded Sample versus Virtual Control Sample (81 couples, averages)**

Variable	Seeded Sample	Control Sample	Simple Ratio	Increases (%)
<b>Lifetime</b>	250 min	200 min	1.25	25
<b>Area</b>	1397 km <sup>2</sup>	1140 km <sup>2</sup>	1.23	23
<b>Volume</b>	6186 km <sup>3</sup>	5057 km <sup>3</sup>	1.22	22
<b>Volume Above 6 km</b>	2315 km <sup>3</sup>	1897 km <sup>3</sup>	1.22	22
<b>Prec.Flux</b>	13 172 m <sup>3</sup> /s	9 900 m <sup>3</sup> /s	1.33	33
<b>Prec.Mass</b>	90 942 kton	56 373 kton	1.61	61

An increase of 61 % in precipitation mass for a control value of 56 373 kton in 81 cases implies:

$$\Delta_2 = 81 \times 0.61 \times 56\,373 \text{ kton} \approx 2\,785\,390 \text{ kton} \approx 2\,258\,951 \text{ ac-f}$$

(mean layer: 24.6 mm  $\approx$  0.97 in)

## Type B Clouds

The sub-sample of 46 type B seeded clouds also received a synergetic analysis. In average the seeding operations on these type B clouds affected 21 % of their whole volume with a quasi-excellent timing (87 % of the material went to the clouds in their first half-lifetime). A total of **1001 AgI and 82 hygroscopic flares** were used in this sub-sample for an effective silver iodide average dose about **90 ice-nuclei per liter**.

Also in average, type B clouds were 118 minutes old when the operations took place; the operation lasted about 32 minutes, and the type B seeded clouds lived 295 minutes (4 hours and 55 minutes)

Table 4 shows the results:

**Table 4: Type B Seeded Sample versus Virtual Control Sample (46 couples, averages)**

Variable	Seeded Sample	Control Sample	Simple Ratio	Increases (%)
<b>Lifetime</b>	295 min	285 min	1.04	4
<b>Area</b>	2102 km <sup>2</sup>	2002 km <sup>2</sup>	1.05	5
<b>Volume</b>	9130 km <sup>3</sup>	8642 km <sup>3</sup>	1.06	6
<b>Volume Above 6 km</b>	2738 km <sup>3</sup>	2587 km <sup>3</sup>	1.06	6
<b>Prec.Flux</b>	14 438 m <sup>3</sup> /s	13 500 m <sup>3</sup> /s	1.07	7
<b>Prec.Mass</b>	121 347 kton	110 372 kton	1.10	10

An increase of 10 % in precipitation mass for a control value of 110 372 kton in 46 cases implies:

$$\Delta_3 = 46 \times 0.10 \times 110\,372 \text{ kton} \approx 507\,711 \text{ kton} \approx 411\,754 \text{ ac-f}$$

(mean layer: 5.3 mm  $\approx$  0.17 in)

**The total increase:  $\Delta = \Delta_1 + \Delta_2 + \Delta_3 = 2\,812\,591 \text{ ac-f} \approx 2.81 \text{ millions ac-f}$**

(~ 790 ac-f per small storm; ~ 27 900 ac-f per large storm; ~ 8 950 per B storms)

## Micro-regionalization

Increases in precipitation mass were analyzed county by county in an attempt to better describe the performance and corresponding results. **Table 5** below offers the details:

**Table 5: Results per county**

### Panhandle Ground Water Conservation District Program

County	Initial seeding	Extended seeding	Acre-feet (increase)	Inches (increase)	Rain gage (season value)	% (increase)
<b>Armstrong</b>	<b>12</b>	<b>15</b>	<b>112 800</b>	<b>2.28</b>	<b>21.11 in</b>	<b>10.8</b>

<b>TPWMA</b>	<b>30</b>	<b>41</b>	<b>265 800</b>	<b>0.43 in</b>	<b>9.36 in</b>	<b>4.7</b>
<b>Totals</b>	<b>306</b>	<b>452</b>	<b>2 586 800 ac-f</b>			
<b>Averages</b>				<b>1.34 in</b>	<b>20.00 in</b>	<b>6.7 %</b>

Outside the target areas (downwind effect): 251 300 ac-f (~ 10 % of the total increase)

**Total amount of flares used: 4248 (AgI) plus 367 (Hygroscopic)**

## Final Comments

1) Results are evaluated as **excellent** (no miss-opportunities, 95 % average timing, 75 in/l average glaciogenic dose).

2) The micro-regionalization analysis showed increases per county; the average increase in precipitation, referred to an average seasonal value, was about **7.0 %**; a total increase of about 2.6 million acre-feet should be considered as a great help to fresh water natural resources.

3) Radar estimations of precipitation should be considered as measurements of trend. Nevertheless, **seeding operations improved the dynamics of seeded clouds**.

4) During the 2016 cloud seeding campaign in Texas, hygroscopic seeding played an important role in the operations. When possible, **it is important to perform dual seeding operations in order to obtain the desire synergy**. Cloud base temperature is an excellent indicator of hygroscopic seeding opportunities: cloud bases colder than about 10 °C may indicate the presence of too many CCN (cloud condensation nuclei) and the needs to potentiate the droplet collision-coalescence mechanism for the formation of precipitation.
